Title: Percutaneous Left Atrial Appendage Closure Devices for Stroke Prevention in Atrial Fibrillation

---

Description/Background

Atrial Fibrillation and Stroke

Atrial fibrillation (AF) is the most common type of irregular heartbeat, affecting at least 2.7 million people in the U.S. Stroke is the most serious complication of AF. The estimated incidence of stroke in nontreated patients with AF is 5% per year. Stroke associated with AF is primarily embolic in nature, tends to be more severe than the typical ischemic stroke, and causes higher rates of mortality and disability. As a result, stroke prevention is a main goal of AF treatment.

Stroke in AF occurs primarily as a result of thromboembolism from the left atrium. The lack of atrial contractions in AF leads to blood stasis in the left atrium, and this low flow state increases the risk for thrombosis. The area of the left atrium with the lowest blood flow in AF, and, therefore, the highest risk of thrombosis, is the left atrial appendage (LAA). It has been estimated that 90% of left atrial thrombi occur in the LAA.

Treatment

Pharmacologic

The main treatment for stroke prevention in AF is anticoagulation, which has proven efficacy. The risk for stroke among patients with AF is evaluated using several factors. Two commonly used scores, the $CHADS_2$ score and the $CHADS_2$-VASc score are described below in Table 1. Warfarin is the predominant agent in clinical use. A number of newer anticoagulant medications, including dabigatran, rivaroxaban, and apixaban, have received U.S. Food and Drug Administration (FDA) approval for stroke prevention in nonvalvular AF and have demonstrated noninferiority to warfarin in clinical trials. While anticoagulation is effective for stroke prevention, it carries an increased risk of bleeding. Also, warfarin requires frequent monitoring and adjustments as well as lifestyle changes. Newer agents to not require the frequent monitoring seen with warfaring therapy; however, specific reversal agents do not exist

for all of these agents. American College of Chest Physicians guidelines (2018), updated from 2012, recommend that CHA_2DS_2VASc be used to evaluated stroke risk, and patients initially identified as having a low risk should not be given antithrombotic therapy. In addition, they recommend bleeding risk assessments be given at every patient contact and that "potentially modifiable bleeding risk factors" should be the initial focus.

Table 1. CHA_2DS_2 and CHA_2DS_2-VASc Scores to Predict Ischemic Stroke Risk in Patients With Atrial Fibrillation

Letter	Clinical Characteristics	Points Awarded
C	Congestive heart failure (signs/symptoms of heart failure confirmed with objective evidence of cardiac dysfunction)	1
H	Hypertension (resting blood pressure >140/90 mmHg on at least 2 occasions or current antihypertensive pharmacologic treatment)	1
A	Age ≥75 y	2
D	Diabetes (fasting glucose >125 mg/dL or treatment with oral hypoglycemic agent and/or insulin)	1
S	Stroke or transient ischemic attack (includes any history of cerebral ischemia)	2
V	Vascular disease (prior myocardial infarction, peripheral arterial disease, or aortic plaque)	1
A	Age 65-74 y	1
Sc	Sex category of female (female sex confers higher risk)	1

Adapted from Lip et al (2018)[3] and January et al (2014).[2]

Bleeding is the primary risk associated with systemic anticoagulation. Risk scores have been developed to estimate the risk of significant bleeding in patients treated with systemic anticoagulation, such as the HAS-BLED score, which has been validated to assess the annual risk of significant bleeding in patients with AF treated with warfarin.[4] The score ranges from 0 to 9, based on clinical characteristics, including the presence of hypertension, renal and liver function, history of stroke, bleeding, labile international normalized ratios, age, and drug/alcohol use. Scores of 3 or greater are considered to be associated with a high risk of bleeding, potentially signaling the need for closer monitoring of patients for adverse risks, closer monitoring of international normalized ratios, or differential dose selections of oral anticoagulants or aspirin.[2]

Surgery

Surgical removal, or exclusion, of the LAA is often performed in patients with AF who are undergoing open heart surgery for other reasons. Percutaneous left atrial appendage closure (LAAC) devices have been developed as a nonpharmacologic alternative to anticoagulation for stroke prevention in AF. The devices may prevent stroke by occluding the LAA, thus preventing thrombus formation.

Several versions of LAA occlusion devices have been developed. The PLAATO system (ev3 Endovascular) was the first device to be approved by FDA for LAA occlusion. The device was discontinued in 2007 for commercial reasons, and intellectual property was sold to manufacturers of the Watchman system. The Watchman Left Atrial Appendage System

(Boston Scientific) is a self-expanding nickel titanium device. It has a polyester covering and fixation barbs for attachment to the endocardium. Implantation is performed percutaneously through a catheter delivery system, using venous access and transseptal puncture to enter the left atrium. Transesophageal echocardiography and fluoroscopy are used to guide the procedure. Following implantation, patients receive anticoagulation with warfarin or alternative agents for approximately 1 to 2 months. After this period, patients are maintained on antiplatelet agents (ie, aspirin and/or clopidogrel) indefinitely. The Watchman FLX device is a next-generation Watchman device that is also FDA-approved for LAAC. This device is based on the design of the Watchman device, is fully recapturable and repositionable, and was made to occlude a wider size range of LAA than the original Watchman device.[5] The Amplatzer cardiac plug (St. Jude Medical), is FDA-approved for closure of atrial septal defects but not for LAAC. A second-generation device, the Amplatzer Amulet, has been developed for the specific indication of LAAC, but does not have currently have FDA approval. The Amplatzer Amulet consists of a nitinol mesh disc to seal the ostium of the LAA and a nitinol mesh distal lobe, to be positioned within the LAA. The device is preloaded within a delivery sheath. The Percutaneous LAA Transcatheter Occlusion device (ev3) has also been evaluated in research studies but has not received FDA approval. The Occlutech® (Occlutech) Left Atrial Appendage Occluder has received a CE mark for coverage in Europe. The Cardioblate® closure device (Medtronic) is currently being tested in clinical studies.

The Lariat Loop Applicator is a suture delivery device approved by the FDA, intended to close a variety of surgical wounds. It is not specifically approved for LAAC. While the Watchman and other devices are implanted in the endocardium, the Lariat is a non-implant epicardial device.

Outcome Measures

The optimal study design for evaluating the efficacy of percutaneous LAAC for the prevention of stroke in AF is a randomized controlled trial (RCT) that includes clinically relevant measures of health outcomes. The rate of ischemic stroke during follow-up is the primary outcome of interest, along with rates of systemic embolization, cardiac events, bleeding complications, and death. For the LAAC devices, the appropriate comparison group could be oral anticoagulation, no therapy (for patients who have prohibitive risk for oral anticoagulation), or open surgical repair.

Although the Watchman device and other LAAC devices would ideally represent an alternative to oral anticoagulation for the prevention of stroke in patients with AF, during the postimplantation period, the device may be associated with increased thrombogenicity and, therefore, anticoagulation is used during the periprocedural period. Most studies evaluating the Watchman device have included patients who are eligible for anticoagulation.

Regulatory Status:

In 2002, the PLAATO system (ev3 Endovascular) was the first device to be approved by the U.S. Food and Drug Administration (FDA) for LAA occlusion. The device was discontinued in 2007 for commercial reasons and intellectual property was sold to manufacturers of the Watchman system.

In 2015, the Watchman™ Left Atrial Appendage Closure Technology (Boston Scientific, Marlborough, MA) was approved by the U.S. Food and Drug Administration (FDA) through the premarket approval process on the basis of the Left Atrial Appendage Versus Warfarin Therapy for Prevention of Stroke in Patients with Atrial Fibrillation (PROTECT-AF) randomized controlled trial.[6] In 2020, the Watchman FLX device (Boston Scientific) was approved by the FDA based on the single-arm, nonrandomized PINNACLE FLX study.[5] These devices are indicated to reduce the risk of thromboembolism from the LAA in patients with nonvalvular AF who:

- Are at increased risk for stroke and systemic embolism based on $CHADS_2$ or CHA_2DS_2-VASc scores and are recommended for anticoagulation therapy;
- Are deemed by their physicians to be suitable for anticoagulation therapy; and
- Have an appropriate rationale to seek a nonpharmacologic alternative to anticoagulation therapy, taking into account the safety and effectiveness of the device compared to anticoagulation therapy.

FDA product code: NGV.

Several other devices are being evaluated for LAA occlusion, but are not approved in the United States for percutaneous LAAC. In 2006, the Lariat® Loop Applicator device (SentreHEART), a suture delivery system, was cleared for marketing by FDA through the 510(k) process. The intended use is to facilitate suture placement and knot tying in surgical applications where soft tissues are being approximated or ligated with a pretied polyester suture. The Amplatzer Amulet® device (St. Jude Medical) and WaveCrest® (Johnson & Johnson Biosense Webster) have CE approval in Europe for LAAC, but are not currently approved in the United States for this indication.

Medical Policy Statement

The safety and effectiveness of a U.S. FDA-approved percutaneous left atrial appendage closure device (eg, Watchman™ Left Atrial Appendage Closure or Watchman FLX) for the prevention of stroke in patients with atrial fibrillation have been established. It may be considered a therapeutic option when indicated.

Inclusionary and Exclusionary Guidelines (Clinically based guidelines that may support individual consideration and pre-authorization decisions)

FDA approved percutaneous left atrial appendage closure devices are considered established when the following criteria are met.

Inclusions:

- There is an increased risk of stroke and systemic embolism based on $CHADS_2$ or CHA_2DS_2-VASc score and systemic anticoagulation therapy is recommended;

AND

- The long term risks of systemic anticoagulation outweigh the risks of the device implantation.

The use of a device with FDA approval for percutaneous left atrial appendage closure (eg, the Watchman™ or the Watchman FLX) for stroke prevention in patients who do not meet the above criteria is considered experimental/investigational.

The use of devices not approved by the U.S. FDA for percutaneous left atrial appendage closure (including but not limited to the Lariat and Amplatzer devices) for stroke prevention in patients with atrial fibrillation is considered experimental/investigational.

POLICY GUIDELINES

The balance of risks and benefits associated with implantation of a U.S. FDA approved percutaneous LAAC device for stroke prevention, as an alternative to systemic anticoagulation, must be made on an individual basis.

Bleeding is the primary risk associated with systemic anticoagulation. A number of risk scores have been developed to estimate the risk of significant bleeding in patients treated with systemic anticoagulation. An example is the HAS-BLED score, which is validated to assess the annual risk of significant bleeding in patients with atrial fibrillation treated with warfarin.[1] Scores range from 0 to 9, based on a number of clinical characteristics (see Table PG1).

Table PG1. Clinical Components of the HAS-BLED Bleeding Risk Score

Letter	Clinical Characteristics	Points Awarded
H	Hypertension	1
A	Abnormal renal and liver function (1 point each)	1 or 2
S	Stroke	1
B	Bleeding	1
L	Labile international normalized ratios	1
E	Elderly (>65 y)	1
D	Drugs or alcohol (1 point each)	1 or 2

Adapted from Pisters et al (2010)[1]
HAS-BLED: Hypertension,Abnormal renal/liver function, Stroke, Bleeding history or predisposition, Labile INR (international normalized ratio), Elderly, Drugs/alcohol concomitantly.

Risk of major bleeding in patients with scores of 3, 4, and 5 has been reported at 3.74 per 100 patient-years, 8.70 per 100 patient-years, and 12.5 per 100 patient-years, respectively. Scores of 3 or greater are considered to be associated with high risk of bleeding, potentially signaling the need for closer monitoring of patients for adverse risks, closer monitoring of international normalized ratio, or differential dose selections of oral anticoagulants or aspirin.[2]

CPT/HCPCS Level II Codes *(Note: The inclusion of a code in this list is not a guarantee of coverage. Please refer to the medical policy statement to determine the status of a given procedure)*

Established codes:

33340

Other codes (investigational, not medically necessary, etc.):

N/A

Note: Individual policy criteria determine the coverage status of the CPT/HCPCS code(s) on this policy. Codes listed in this policy may have different coverage positions (such as established or experimental/investigational) in other medical policies.

Rationale

Evidence reviews assess the clinical evidence to determine whether the use of a technology improves the net health outcome. Broadly defined, health outcomes are length of life, quality of life, and ability to function—including benefits and harms. Every clinical condition has specific outcomes that are important to patients and managing the course of that condition. Validated outcome measures are necessary to ascertain whether a condition improves or worsens; and whether the magnitude of that change is clinically significant. The net health outcome is a balance of benefits and harms.

To assess whether the evidence is sufficient to draw conclusions about the net health outcome of a technology, 2 domains are examined: the relevance and the quality and credibility. To be relevant, studies must represent 1 or more intended clinical use of the technology in the intended population and compare an effective and appropriate alternative at a comparable intensity. For some conditions, the alternative will be supportive care or surveillance. The quality and credibility of the evidence depend on study design and conduct, minimizing bias and confounding that can generate incorrect findings. The randomized controlled trial (RCT) is preferred to assess efficacy; however, in some circumstances, nonrandomized studies may be adequate. RCTs are rarely large enough or long enough to capture less common adverse events and long-term effects. Other types of studies can be used for these purposes and to assess generalizability to broader clinical populations and settings of clinical practice.

The evidence on the efficacy of left atrial appendage closure (LAAC) devices consists of numerous observational studies of various occlusion devices, and 2 published RCTs of the Watchman device, the Watchman Left Atrial Appendage System for Embolic Protection in Patients with Atrial Fibrillation (PROTECT AF) and Prospective Randomized Evaluation of the Watchman LAA Closure Device in Patients With Atrial Fibrillation (AF) Versus Long Term Warfarin Therapy (PREVAIL) trials, that compared LAAC with warfarin anticoagulation . Evidence on each device will be reviewed separately, because the devices are not similar in design and each may have its own unique considerations.

WATCHMAN DEVICE

Clinical Context and Therapy Purpose

The purpose of the Watchman device in patients who have atrial fibrillation (AF) and are at increased risk for embolic stroke is to provide a treatment option that is an alternative to or an improvement on existing therapies.

The question addressed in this evidence review is: Does the use of the Watchman device improve the net health outcome compared with systemic anticoagulation treatment in patients with AF who are at increased risk for embolic stroke?

The following PICO was used to select literature to inform this review.

Patients

The relevant population of interest is patients with atrial fibrillation (AF). AF causes a low flow state in the left atrium which increases the risk of thromboembolism. Strokes in patients with AF occur primarily due to thromboembolism from the left atrium. Patients with AF who are not treated have a 5% estimated incidence of stroke.

Interventions

The therapy being considered is use of the Watchman percutaneous LAAC device and the Watchman FLX device (a next generation device based on the design of the original Watchman device).[5] The devices are made of nickel titanium and are implanted percutaneously through a catheter, into the left atrium. The Watchman devices come in 5 sizes and self-expand to occlude the LAA. By occluding the LAA, thrombus formation is prevented, potentially preventing stroke. Following implantation of the device, the patient receives anticoagulation for 1 to 2 months. Once it is established that there is no peridevice leak or thrombus development, he patient is then placed on antiplatelet agents indefinitely.

LAAC is performed by a cardiac surgeon under general anesthesia (although it is not invasive surgery) in an outpatient surgical setting.

Comparators

The current treatment for stroke prevention in patients with AF is systemic anticoagulation. While anticoagulants are effective in preventing stroke, the increased risk of bleeding is a potential harm. Warfarin, which is the most common anticoagulant in use, requires frequent monitoring and lifestyle changes. Other anticoagulants, found to be noninferior to warfarin, include dabigatran, rivaroxaban, and apixaban.

Patients with AF are actively managed by a cardiologist.

Outcomes

The general outcomes of interest are rates of ischemic or hemorrhagic stroke, cardiovascular or unexplained death, and systemic embolism, measured between 6 to 12 months of followup, although some studies show follow-up of up to 5 years.[6] Additional outcomes of interest include device- or procedure-related events that may occur within 1 week of the procedure. In particular, events requiring open cardiac surgery or major endovascular intervention (eg,

pseudoaneurysm repair, arteriovenous fistula repair, or other major endovascular repair) should be noted.

Study Selection Criteria

Methodologically credible studies were selected using the following principles:

- To assess efficacy outcomes, comparative controlled prospective trials were sought, with preference for RCTs;
- In the absence of such trials, comparative observational studies were sought, with preference for prospective studies;
- To assess longer term outcomes and adverse effects, single-arm studies that capture longer periods of follow up and/or larger populations were sought;
- Studies with duplicative or overlapping populations were excluded.

REVIEW OF EVIDENCE

Systematic Reviews

A Blue Cross Blue Shield Association TEC Assessment (2014) evaluated the use of the Watchman device for patients eligible and ineligible for anticoagulation therapy.[8] The Assessment determined that the device did not meet TEC criteria. The Assessment made the following conclusions about the use of LAAC in patients without contraindications to anticoagulation:

> "We identified 2 randomized controlled trials (RCTs) and 1 case series evaluating the Watchman™ device. The RCTs were noninferiority trials and compared LAAC with anticoagulation. The first trial showed a lower rate of a composite outcome (stroke, death, and embolism) in patients receiving LAAC and met noninferiority criteria compared with anticoagulation, but FDA review noted problems with patient selection, potential confounding with other treatments, and losses to follow-up. The second trial, which incorporated the first trial's results as a discounted informative prior in a Bayesian analysis, showed similar rates of the same composite outcome but did not meet noninferiority criteria. The second trial met its second principal outcome noninferiority criteria in 1 of 2 analyses and a performance goal for short-term complication rate. When assessing the results of both trials, the relative performance of LAAC and anticoagulation is uncertain."

A number of systematic reviews published after the TEC Assessment have combined the results of the available RCTs.[9-16] Others have included RCTs and observational studies.[12,17,18]

Holmes et al (2015) published the most rigorous meta-analysis.[11] This analysis included patient-level data from the industry-sponsored PROTECT-AF and PREVAIL trials (described below), together with both studies' continued access registries. The PROTECT AF and PREVAIL registries were designed to include patients with similar baseline characteristics as their respective RCTs. The meta-analysis included 2406 patients, 1877 treated with the Watchman device and 382 treated with warfarin alone. Mean patient follow-up durations were 0.58 years and 3.7 years, respectively, for the PREVAIL continued access registry and the PROTECT AF continued access registry. In a meta-analysis of 1114 patients treated in the RCTs, compared with warfarin, LAAC met the trial's noninferiority criteria for the primary composite efficacy end point of all-cause stroke, systemic embolization, and cardiovascular death (hazard ratio [HR], 0.79, 95% confidence interval [CI], 0.52 to 1.2; p=0.22). All-cause

stroke rates did not differ significantly between groups (1.75 per 100 patient-years for LAAC vs 1.87 per 100 patient-years for warfarin; HR=1.02; 95% CI, 0.62 to 1.7; p=0.94). LAAC-treated patients had higher rates of ischemic stroke (1.6 events per 100 patient-years vs 0.9 events per 100 patient-years; HR=1.95, p=0.05) when procedure-related strokes were included, but had lower rates of hemorrhagic stroke (0.15 events per 100 patient-years vs 0.96 events per 100 patient-years; HR=0.22; 95% CI, 0.08 to 0.61; p=0.004).

Price et al (2015) reported on a second patient-level meta-analysis of the 2 RCTs that focused on bleeding outcomes.[14] There were 54 episodes of major bleeding, with the most common types being gastrointestinal (GI) bleed (31/54 [57%]) and hemorrhagic stroke (9/54 [17%]). On combined analysis, the rate of major bleeding episodes over the entire study period did not differ between groups. There were 3.5 events per 100 patient-years in the Watchman group compared with 3.6 events per 100 patient-years in the anticoagulation group, for a rate ratio of 0.96 (95% CI, 0.66 to 1.40; p=0.84). However, there was a reduction in bleeding risk for the Watchman group past the initial periprocedural period. For bleeding events occurring more than 7 days postprocedure, the event rates were 1.8 per 100 patient-years in the Watchman group compared with 3.6 per 100 patient-years in the anticoagulation group (rate ratio, 0.49; 95% CI, 0.32 to 0.75; p=0.01). For bleeding events occurring more than 6 months postprocedure (the time at which antiplatelet therapy is discontinued for patients receiving the Watchman device), the event rates were 1.0 per 100 patient-years in the Watchman group compared with 3.5 per 100 patient-years in the anticoagulation group (rate ratio, 0.28; 95% CI, 0.16 to 0.49; p<0.001).

Additional systematic reviews have used network meta-analyses to compare Watchman device with novel oral anticoagulants (6 RCTs, N=59,627 subjects),[19] and have compared percutaneous LAA occlusion (5 RCTs, N=1285 subject) with standard anticoagulant or antiplatelet therapy with device-based surgical or percutaneous LAA exclusion.[20] Bajaj et al (2016) published the network meta-analysis comparing vitamin K antagonists with novel oral anticoagulants and with the Watchman device.[19] They reported that all the treatment strategies had comparable ischemic stroke rates. However, the cluster analyses showed the novel oral anticoagulants ranked best in safety and efficacy, followed by vitamin K antagonists, and then the Watchman device. Interpretation of these results is limited by the small sample sizes and population heterogeneity in the RCTs comparing the Watchman with vitamin K antagonists. The network meta-analysis comparing LAAC with oral anticoagulants, antiplatelets, and placebo, reported a trend in stroke and mortality favoring LAAC, but the differences were not statistically significant.[20] The authors noted that overall quality of the evidence was low.

Baman et al (2018) conducted a systematic review of LAAC devices, including Watchman, Amplatzer cardiac plug, Amplatzer Amulet, and Lariat devices.[21] The literature search, conducted through April 2017, identified 2 RCTs and 15 registry studies. No meta-analyses were conducted. The authors concluded that the Watchman may be noninferior to warfarin and that long term efficacy outcomes are promising. For the remaining devices included in the review, the authors note that high quality prospective studies comparing the devices to each other and with anticoagulants are needed.

Randomized Controlled Trials

PROTECT AF Trial

The first RCT published was PROTECT AF, an unblinded randomized trial evaluating the noninferiority of a LAAC device compared with warfarin for stroke prevention in AF.[22] The trial randomized 707 patients from 59 centers in the U.S. and Europe to the Watchman device or to warfarin treatment in a 2:1 ratio. Mean follow-up was 18 months. The primary efficacy outcome was a composite end point of stroke (ischemic or hemorrhagic), cardiovascular or unexplained death, or systemic embolism. There was also a primary safety outcome, a composite end point of excessive bleeding (intracranial or GI bleeding) and procedure-related complications (pericardial effusion, device embolization, procedure-related stroke).

The primary efficacy outcome occurred at a rate of 3.0 per 100 patient-years in the LAAC group compared with 4.9 per 100 patient-years in the warfarin group (rate ratio, 0.62; 95% credible interval [CrI], 0.35 to 1.25). Based on these outcomes, the probability of noninferiority was greater than 99.9%. For the individual components of the primary outcome, cardiovascular/unexplained death and hemorrhagic stroke were higher in the warfarin group. By contrast, ischemic stroke was higher in the LAAC group at 2.2 per 100 patient-years compared with 1.6 per 100 patient-years in the warfarin group (rate ratio, 1.34; 95% CrI, 0.60 to 4.29).

The primary safety outcome occurred more commonly in the LAAC group, at a rate of 7.4 per 100 patient-years compared with 4.4 per 100 patient-years in the warfarin group (rate ratio, 1.69; 95% CrI, 1.01 to 3.19). The excess in adverse event rates for the LAAC group was primarily the result of early adverse events associated with placement of the device. The most frequent type of complication related to LAAC device placement was pericardial effusion requiring intervention, which occurred in 4.8% (22/463) of patients.

Reddy et al (2013) reported on longer term follow-up from the PROTECAF trial.[23] At a mean follow-up of 2.3 years, the results were similar to the initial report. The relative risk for the composite primary outcome in the Watchman group compared with anticoagulation was 0.71, and this met noninferiority criteria with a confidence greater than 99%. Complications were more common in the Watchman group, with an estimated rate of 5.6% per year in the Watchman group compared with 3.6% per year in the warfarin group.

Reddy et al (2014) also reported outcomes through 4 years of follow-up.[24] Mean follow-up was 3.9 years in the LAAC group and 3.7 years in the warfarin group. In the LAAC group, warfarin was discontinued in 345 (93.2%) of 370 patients by the 12-month follow-up evaluation. During the follow-up period, the relative risk for the composite primary outcome in the Watchman group compared with anticoagulation was 0.60 (8.4% in the device group vs 13.9% in the anticoagulation group; 95% CI, 0.41 to 1.05), which met the noninferiority criteria with a confidence greater than 99.9%. Fewer hemorrhagic strokes (0.6% vs 4.0%; rate ratio, 0.15; 95% CrI, 0.03 to 0.49) and fewer cardiovascular events (3.7% vs 0.95%; rate ratio, 0.40; 95% CrI, 0.23 to 0.82) occurred in the Watchman group. Rates of ischemic stroke did not differ significantly between groups, but Watchman patients had lower all-cause mortality than anticoagulation patients (12.3% vs 18.0%; HR=0.66; 95% CI, 0.45 to 0.98; p=0.04).

Alli et al (2013) reported quality-of-life parameters, as measured by change in Short-Form 12-Item Health Survey scores from baseline to 12 months of follow-up, for a subset of 547 subjects in the PROTECT AF trial.[25] For the subset of PROTECT AF subjects included in the Alli analysis, at baseline, control group subjects had a higher mean $CHADS_2$ score (2.4 vs 2.2; p=0.052) and were more likely to have a history of coronary artery disease (49.5% vs 39.6%; p=0.028). For subjects in the Watchman group, the 12-Item Short-Form Health Survey total physical score improved in 34.9% and was unchanged in 29.9%; for those in the warfarin group, the total physical score improved in 24.7% and was unchanged in 31.7% (p=0.01).

Reddy et al (2017) published 5-year follow-up results, indicating that the LAAC group had significantly lower rates of the composite efficacy end point (stroke, systemic embolism, cardiovascular death) compared with the warfarin-only group (p=0.04).[7]

PREVAIL Trial

A second RCT, the PREVAIL trial, was conducted after the 2009 FDA decision on the Watchman device to address some limitations of the PROTECT AF trial, including its inclusion of patients with low stroke risk ($CHADS_2$ scores of 1), high rates of adjunctive antiplatelet therapy use in both groups, and generally poor compliance with warfarin therapy in the control group. Holmes et al (2014) published results from the PREVAIL trial.[26] In the PREVAIL trial, 461 subjects enrolled at 41 sites were randomized in a 2:1 fashion to the Watchman device or control, which consisted of either initiation or continuation of warfarin therapy with a target international normalized ratio of 2.0 to 3.0. Subjects had nonvalvular AF and required treatment for prevention of thromboembolism based on a CHADS2 score of 2 or higher (or ≥1 with other indications for warfarin therapy based on American College of Cardiology, American Heart Association, and European Society of Cardiology joint guidelines) and were eligible for warfarin therapy. In the device group, warfarin and low-dose aspirin were continued until 45 days postprocedure; if a follow-up echocardiogram at 45 days showed occlusion of the LAA, warfarin therapy could be discontinued. Subjects who discontinued warfarin were treated with aspirin and clopidogrel for 6 months after device implantation and with aspirin 325 mg indefinitely after that.

Three noninferiority primary efficacy end points were specified: (1) occurrence of ischemic or hemorrhagic stroke, cardiovascular or unexplained death, and systemic embolism (18-month rates); (2) occurrence of late ischemic stroke and systemic embolization (beyond 7 days postrandomization, 18-month rates); and (3) occurrence of all-cause death, ischemic stroke, systemic embolism, or device- or procedure-related events requiring open cardiac surgery or major endovascular intervention (eg, pseudoaneurysm repair, arteriovenous fistula repair, or other major endovascular repair) occurring within 7 days of the procedure or by hospital discharge, whichever was later. The 18-month event rates were determined using Bayesian statistical methods to integrate data from the PROTECT AF trial. All patients had a minimum follow-up of 6 months. For randomized subjects, mean follow-up was 11.8 months and median follow-up was 12.0 months (range, 0.03 to 25.9 months).

For the first composite primary end point, the 18-month modeled rate ratio between the device and control groups was 1.07 (95% CrI, 0.57 to 1.89). Because the upper bound of the 95% credible interval was above the preset noninferiority margin of 1.75, the noninferiority criteria were not met. For the second primary end point of late ischemic stroke and systemic embolization, the 18-month relative risk between the device and control groups was 1.6 (95%

CrI, 0.5 to 4.2), with an upper bound of the 95% credible interval above the preset noninferiority margin of 2.0. The rate difference between the device and control groups was 0.005 (95% CrI, -0.019 to 0.027). The upper bound of the 95% credible interval was lower than the noninferiority margin of 0.0275, so the noninferiority criterion was met for the rate difference. For the third primary end point (major safety issues), the noninferiority criterion was met.

Reddy et al (2017), in their 5-year follow-up results, indicated that the Watchman device was noninferior to warfarin alone in the composite efficacy end point (stroke, systemic embolism, cardiovascular death) (p=0.5).[7]

Reddy et al (2017), in addition to providing 5-year final results for the individual trials, also conducted a meta-analysis of the 5-year outcomes using data from both trials.[7] Meta-analytic results are summarized in Table 2, showing that the Watchman device is noninferior to warfarin alone in stroke prevention among patients with nonvalvular AF. Also, patients treated with the Watchman device experienced significantly lower bleeding and mortality compared with patients receiving warfarin.

Table 2. Five-Year Meta-Analytics Results for the PROTECT AF and PREVAIL AF Trials

Outcomes	Watchman, n (Rate per 100 PY), %	Warfarin Alone, n (Rate per 100 PY),%	HR (95% CI)	p-value
Composite stroke/SE/CV death	79 (2.8)	50 (3.4)	0.8 (0.6 to 1.2)	.3
All stroke or SE	49 (1.7)	27 (1.8)	1.0 (0.6 to 1.5)	.9
CV/unexplained death	39 (1.3)	33 (2.2)	0.6 (0.4 to 0.9)	.03
All cause death	106 (3.0)	73 (4.9)	0.7 (0.5 to 1.0)	.03
Major bleeding, all	85 (3.1)	50 (3.5)	0.9 (0.6 to 1.3)	.6
Major bleeding, non-LAAC-related	48 (1.7)	51 (3.6)	0.5 (0.3 to 0.7)	<.001

CI: confidence interval; CV: cardiovascular; HR: hazard ratio; LAAC: left atrial appendage closure; PREVAIL: Prospective Randomized Evaluation of the Watchman LAA Closure Device in Patients With Atrial Fibrillation (AF) Versus Long Term Warfarin Therapy; PROTECT AF: Watchman Left Atrial Appendage System for Embolic Protection in Patients With Atrial Fibrillation; PY: patient-years; SE: systemic embolism.

PRAGUE-17 Trial

Osmancik et al (2020) published the LAAC versus Novel Anticoagulation Agents in AF (PRAGUE-17) study, a multicenter, randomized, noninferiority study that compared use of LAAC to direct oral anticoagulants in high risk patients with nonvalvular AF.[27] Patients were included if they had a history of bleeding requiring intervention or hospitalization, history of cardioembolic event while taking an anticoagulant, or CHA2DS2-VASc score ≥3 with a HAS-BLED score ≥2. Patients either received LAAC (n=181) with either the Amulet or Watchman/ Watchman FLX devices based on discretion of the implanting center, or a direct oral anticoagulant (rivaroxaban, apixaban, or dabigatran) (n=201).

The primary endpoint was a composite of ischemic or hemorrhagic stroke or TIA, systemic embolism, clinically significant bleeding, cardiovascular death, or significant peri-procedural or

device-related complications. At baseline, the mean CHA2DS2-VASc score was 4.7 and HAS-BLED score was 3.1. Follow-up was 20.8 months. Of the LAAC group, 61.3% received an Amulet, 35.9% received a Watchman device, and 2.8% received a Watchman-FLX device. The primary endpoint occurred in 41 patients (47 events) in the direct oral anticoagulant group (13.42 event rate per year) compared to 35 patients (38 events) in the LAAC group (10.99 event rate per year) (subdistribution HR, 0.84; 95% CI, 0.53 to 1.21; p-value for noninferiority, p=0.004). All stroke/TIA events occurred in 9 patients (9 events) in each group, subdistribulation HR, 1.0 (95% CI, 0.40 to 2.51). Results were not divided by type of LAAC device received. Significant procedure- or device-related complications occurred in 9 patients in the LAAC group. Early complications (≤ 7 days) included device embolization (n=1), procedure-related death (n=1), and vascular complications (n=2), while late complications (> 7 days) included pericardial effusion (n=2), device-related death (n=1), and other complications (n=2). The procedure-related death was due to a femoral vascular access bleed and myocardial infarction. The device-related death occurred with the Amulet device due to a pericardial effusion approximately 6 weeks after the procedure.

Chun et al (2013) compared the Watchman device with the Amplatzer cardiac plug among patients who had nonvalvular AF, were at high risk for stroke, and had a contraindication to or were unwilling to take oral anticoagulants.[28] Eighty patients were randomized to LAA occlusion with the Watchman or the Amplatzer device. After device implantation, either preexisting oral anticoagulation therapy or dual-platelet inhibition with aspirin and clopidogrel was continued for 6 weeks. There were no statistically significant differences in procedure time, fluoroscopy time, or major safety events between the 2 groups. At a median follow-up of 364 days, there were no cases of stroke, transient ischemic attack, or other bleeding complications.

Nonrandomized Studies

Numerous case series and nonrandomized studies have been published.[29-33] Several are notable in that they were conducted in patients not eligible for anticoagulation, a population not included in PROTECT AF and PREVAIL. Reddy et al (2013) conducted a multicenter, prospective, nonrandomized trial to evaluate the safety and efficacy of LAAC with the Watchman device in patients with nonvalvular AF with a $CHADS_2$ score 1 or higher who were considered ineligible for warfarin.[24] Postimplantation, patients received 6 months of clopidogrel or ticlopidine and lifelong aspirin therapy. Thirteen (8.7%) patients had a procedure- or device-related serious adverse event, most commonly pericardial effusion (3 patients). Over a mean follow-up of 14.4 months, all-cause stroke or systemic embolism occurred in 4 patients.

The EWOLUTION Watchman registry tracks procedural success, long-term outcomes, and adverse events in real-world settings. This registry compiles data from patients receiving the Watchman device at 47 centers in 13 countries. Boersma et al (2016) conducted an analysis of the EWOLUTION registry data, reporting 30-day outcomes after device implantation in 1021 patients.[35] The overall population had a risk of bleeding that was substantially higher than that for patients in the RCTs. Over 62% of patients included in the registry were deemed ineligible for anticoagulation by their physicians. Approximately one-third of patients had a history of major bleeding, and 40% had HAS-BLED scores of 3 or greater, indicating moderate-to-high risk of bleeding. Procedural success was achieved in 98.5% of patients, and 99.3% of implants demonstrated no blood flow or minimal residual blood flow postprocedure. Serious adverse events due to the device or procedure occurred at an overall rate of 2.8% (95% CI, 1.9% to

4.0%) at 7 days and 3.6% (95% CI, 2.5% to 4.9%) at 30 days. The most common serious adverse event was major bleeding.

Dukkipati et al (2018) studied the incidence, predictors, and clinical outcomes of device-related thrombus (DRT) among the following patients receiving the Watchman in the following trials and registries: PROTECT AF, PREVAIL, Continued Access to PROTECT AF registry, and Continued Access to PREVAIL registry.[36] Surveillance transesophageal electrocardiograms were conducted in all patients at 45 days and 12 months. Patients in the RCTs also received the electrocardiograms at 6 months. A total of 1739 patients were followed for a total of 7159 patient-years. Mean age of the population was 74 years and 34% were women. DRT was detected in 65 (3.7%) of the patients. Stroke or systemic embolism rates were 7.5 and 1.8 per 100 patient-years for patients with and without DRT, respectively. A multivariable modeling analysis found the following predictors of DRT: history of transient ischemic attack or stroke, permanent atrial fibrillation, vascular disease, LAA diameter, and left ventricular ejection fraction.

Jazayeri et al (2018) evaluated the safety profiles of the Watchman and the Lariat devices, using the FDA's Manufacturer and User Facility Device Experience (MAUDE) database from 2009 to 2016.[37] MAUDE consists of mandatory reports from manufacturers and voluntary reports from healthcare professionals and patients. Outcomes assessed included: a composite of stroke/TIA, pericardiocentesis, cardiac surgery, and death; DRT; cardiac surgery; and myocardial infarction. A total of 5849 Watchman devices were implanted, with 472 events reported during the study period. The most common events in patients receiving the Watchman, were device malfunction (97 [1.7%]), pericardial effusion (84 [1.4%]), need for pericardiocentesis (57 [0.97%]), and intracardiac thrombus (47 [0.84%]). Twenty deaths were reported in the Watchman group, with 1 likely related to DRT. Compared with the Lariat device, the composite outcome occurred significantly more in the group receiving the Watchman than with in the group receiving the Lariat, 1.9% versus 1.1%, p=0.001). Analysis results for the Lariat device will be discussed in the next section, "Other Closure Devices".

Section Summary: Watchman Device

The most relevant evidence on use of the Watchman device for LAAC in patients eligible for anticoagulation derives from 2 industry-sponsored RCTs comparing Watchmen and systemic anticoagulants and a patient-level meta-analysis of those studies. After 5 years of follow-up, meta-analytic results showed that the ischemic stroke risk beyond 7 days did not differ between groups and that the hemorrhagic stroke risk remained significantly lower in the LAAC group. The results showed that the Watchman device is noninferior to warfarin alone in stroke prevention among patients with nonvalvular AF. In addition, patients treated with the Watchman device experienced significantly lower bleeding and mortality. A large study of patients receiving the Watchman device (combining patients from the 2 RCTs and 2 registries) reported that patients who developed DRT were 4 times more likely to experience a stroke or systemic embolism. The authors suggest a surveillance strategy for patients at high risk of DRT following Watchman implantation. One RCT found use of LAAC with either the Watchman device or Amplatzer Amulet device noninferior to direct oral anticoagulants for high-risk patients with AF; however, subgroup analyses by type of LAAC device were not performed, limiting interpretation.

OTHER CLOSURE DEVICES

Clinical Context and Therapy Purpose

The purpose of other LAAC devices in patients who have atrial fibrillation and are at increased risk for embolic stroke is to provide a treatment option that is an alternative to or an improvement on existing therapies.

The question addressed in this evidence review is: Does the use of other LAAC devices improve the net health outcome compared with systemic anticoagulation treatment in patients with atrial fibrillation who are at increased risk for embolic stroke?

The following PICO was used to select literature to inform this review.

Patients

The relevant population of interest is patients with atrial fibrillation (AF). AF causes a low flow state in the left atrium which increases the risk of thromboembolism. Strokes in patients with AF occur primarily due to thromboembolism from the left atrium. Patients with AF who are not treated have a 5% estimated incidence of stroke.

Interventions

- The interventions of interest are other LAA occlusion devices. By occluding the LAA, thrombus formation is prevented, potentially preventing stroke. Other devices currently being evaluated for the use of LAA occlusion include: The Lariat Loop Applicator is a suture delivery device approved by the FDA to facilitate suture placement and knot tying for use in surgical applications where soft tissues are being approximated or ligated with a pre-tied polyester suture. The approved use does not specify LAA occlusion. While the Watchman and other devices are implanted in the endocardium, the Lariat is a non-implant epicardial device. The Lariat is contraindicated in patients with active pericarditis; prior sternotomy or other mediastinal surgery or known pericardial adhesions; appendage width >45 mm; superiorly oriented appendage lying near or behind the pulmonary arterial trunk; or appendage thrombus.
- The Amplatzer Amulet device comes in 8 sizes to accommodate various patient anatomies. The mechanism of action is similar to the Watchman. Following implantation of the Amulet, patients are placed on antiplatelet agents and do not need warfarin. There is an ongoing trial comparing the Amplatzer Amulet with the Watchman (NCT03399851).

Comparators

The current treatment for stroke prevention in patients with AF is systemic anticoagulation. While anticoagulants are effective in preventing stroke, the increased risk of bleeding is a potential harm. Warfarin, which is the most common anticoagulant in use, requires frequent monitoring and lifestyle changes. Other anticoagulants, found to be noninferior to warfarin include dabigatran, rivaroxaban, and apixaban.

Patients with AF are actively managed by a cardiologist.

Outcomes

The general outcomes of interest are rates of ischemic or hemorrhagic stroke, cardiovascular or unexplained death, and systemic embolism, measured between 6 to 12 months of follow up,

although some studies show follow up of up to 5 years. Additional outcomes of interest include device- or procedure-related events that may occur within 1 week of the procedure, in particular, events requiring open cardiac surgery or major endovascular intervention (eg, pseudoaneurysm repair, arteriovenous fistula repair, or other major endovascular repair).

Study Selection Criteria

Methodologically credible studies were selected using the following principles:

- To assess efficacy outcomes, comparative controlled prospective trials were sought, with preference for RCTs;
- In the absence of such trials, comparative observational studies were sought, with preference for prospective studies;
- To assess longer term outcomes and adverse effects, single-arm studies that capture longer periods of follow up and/or larger populations were sought;
- Studies with duplicative or overlapping populations were excluded.

REVIEW OF EVIDENCE

Lariat Device

Systematic Review

Chatterjee et al (2015) published a systematic review of studies on the Lariat device.[38] No RCTs were identified. Five case series or observational studies were included, with a total of 309 patients (range, 4 to 154 patients).[39,40,41,42,43] The combined estimate of procedural success was 90.3%. One (0.3%) death was reported and 7 (2.3%) patients required urgent cardiac surgery. Reviewers also searched the MAUDE database for adverse events, and found 35 unique reports. Among the 35 reported complications, there were 5 deaths and 23 cases of emergency cardiac surgery.

Observational Studies

Individual observational studies published since the systematic review include a large 2016 observational study of 712 consecutive patients from 18 U.S. hospitals.[44] This study reported a procedural (suture deployment) success rate of 95% and complete closure rate in 98%. The high success rate was attributed to the appropriate selection of patients for the procedure, which was determined by a screening computed tomography scan showing if the LAA anatomy was suitable for LARIAT deployment. There was 1 death, and emergent cardiac surgery was required in 1.4%. Cardiac perforations (overall and those needing surgery) and number of patients needing blood transfusions decreased when providers altered the procedure from using large bore needles to micropuncture needles. Other individual observational studies are smaller, reporting success rates and complication rates in the same range.[45,46,47,48]

Litwinowicz et al (2018) presented an observational study of 139 patients from a single center undergoing LAAC with the Lariat device, with a longer follow-up than the other observational studies.[49] After a follow up of 5 years (428 patient-years), the thromboembolism rate was 0.8%, with a calculated bleeding risk reduction of 78%. The overall mortality rate was 1.6%. Litwinowicz et al (2019) reported on the same set of patients, dividing them into 2 groups: patients with prior stroke (n=37) and those without prior stroke (control group; n=102).50 Results showed that patients in the stroke group had significantly higher $CHADS_2$, CHA_2-DS_2-VASc, and HAS-BLED scores than the control group (all $p<0.0001$). Thromboembolic event rate, bleeding event rate, and mortality rate were not significantly different between groups.

The investigators concluded that patients with prior stroke may be preferred for LAAC, regardless of whether a contraindication for anticoagulant therapy exists.

Nonrandomized Comparative Study
Jazayeri et al (2018) evaluated the safety profiles of the Watchman and the Lariat devices, using the FDA's MAUDE database from 2009 to 2016.[37] A total of 4889 Lariat devices were implanted, with 136 events reported during the study period. The most common events in the Lariat group were pericardial effusion (46 [0.94%]), need for cardiac surgery (38 [0.78%]), and pericardiocentesis (23 [0.47%]). Ten deaths were reported in the Lariat group, with 6 involving tightening of the suture around the LAA. Compared to the Watchman device, the composite outcome occurred significantly more in the group receiving the Watchman than in the group receiving the Lariat, 1.9% versus 1.1%, p=0.001.

Litwinowicz et al (2019) compared outcomes of patients undergoing LAAC device with the Lariat device (n=57) with patients receiving either warfarin or clopidogrel (n=31).[51] Age, sex, and comorbidities were similar between the 2 groups. Treatment prior to the study differed significantly. The Lariat group received warfarin (93%), aspirin (4%), aspirin plus clopidogrel (2%) and no anticoagulation (1%). The control group received warfarin (87%) or clopidogrel (13%). However, there was no significant difference in CHA2DS2-VAS scores between the groups at baseline. Average followup in the Lariat group was 59 months and average followup in the control group was 60 months. There were no thromboembolic events in the Lariat group, while 9.6% of the control group experienced thromboembolic events (p=0.02). The bleeding risk reduction in the Lariat group was estimated at 53%.

Section Summary: Lariat Device
There are no RCTs of the Lariat device for LAAC. There was 1 non-randomized study comparing patients undergoing LAAC with the Lariat device with patients receiving either anticoagulant or antiplatelet therapy. Results showed significantly fewer thromboembolic events in the group undergoing LAAC with the Lariat device compared with the group receiving medication alone. The remaining evidence consisted of observational studies. The evidence is insufficient to draw conclusions about treatment efficacy.

Amplatzer Cardiac Plug Device and Amplatzer Amulet Device

Amplatzer Cardiac Plug (first generation)
The available evidence on use of the Amplatzer device for left atrial occlusion consists of a number of observational studies. Nietlispach et al (2013) published the largest series , which included 152 patients from a single institution in Europe.[52] Short-term complications occurred in 9.8% (15/152) of patients. The longer-term adverse outcomes occurred in 7% of patients, including 2 strokes, 1 peripheral embolization, and 4 episodes of major bleeding. Device embolization occurred in 4.6% (7/152) of patients. Other reports of patients treated with the Amplatzer device include a study of 90 patients from Belgium (2013),[53] 86 patients from Portugal (2012),[54] 37 patients from Italy (2013),[55] 35 patients from Spain (2013),[56] 21 patients from Poland (2013),[57] and 20 patients from China (2012).[29] All studies reported high procedural success rates, as we;; as various complications such as vascular complications, air embolism, esophageal injury, cardiac tamponade, and device embolization.

Cruz-Gonzales et al (2020), in their retrospective registry study, aimed to evaluate the safety and efficacy of LAA occlusion for patients with nonvalvular AF with prior stroke or TIA despite anticoagulant therapy (resistant stroke [RS]).[58] They assessed data from the Amplatzer Cardiac Plug multicenter registry on 1047 consecutive patients with nonvalvular AF undergoing LAA occlusion. Out of the 1047, 115 had RS and 932 had other indications. There were no significant differences in baseline characteristics between the 2 groups. The RS group had a significantly higher mean CHA2-DS2-VASc score (5.5±1.5 in the RS group vs. 4.6±1.6 in the non-stroke group; p<0.001) and HAS-BLED score (3.9±1.3 vs. 3.1±1.2; p<0.001). There were no significant differences between groups in procedural success or periprocedural major safety events (7.8% vs. 4.5%; p=.1). All patients completed at least 1 year of follow-up. At follow-up, the observed annual rate of stroke or TIA was 2.6% (65% relative reduction of thromboembolism based on the CHA2-DS2-VASc score) in the RS group and 1.2% (78% relative risk reduction) for the non-stroke group. In addition, the observed annual major bleeding rate was 0% (100% relative reduction based on the HAS-BLED score) for RS patients and 1.2% (79% relative reduction) for those without prior stroke/TIA. Although larger controlled trials are needed, LAA occlusion showed significant benefit to patients who had had a previous stroke or TIA.

Several other observational studies have reported the use of the Amplatzer device in patients with a contraindication to oral anticoagulation therapy. Santoro et al (2016), in the larges observational study, reported outcomes up to 4 years postprocedure for 134 patients with nonvalvular AF and a long-term contraindication to oral anticoagulation treated with the Amplatzer device.[59] Patients had a median CHA_2DS_2-VASc score of 4 and were generally considered at high risk for bleeding complications. Procedural success occurred in 93.3%, and 3 major procedure-related complications (2 cases of cardiac tamponade, 1 case of pericardial effusion requiring drainage or surgery) occurred. Over a mean follow-up of 680 days, observed annual rates of ischemic strokes and any thromboembolic events were 0.8% and 2.5%, respectively. Other observational studies have been published in this population, ranging from 37 to 100 patients.[55,60,61,62,63] They also reported high success rates and low procedural complications.

Amplatzer Amulet (second generation)

A second generation device, the Amplatzer Amulet was developed to potentially lower device embolization rates, simplify the technical implantation procedure, and lower severe complication rates. The Amulet first became available in Europe in January 2013. Below are descriptions of studies comparing the amulet with the first generation cardiac plug. There is currently an ongoing trial comparing the Amplatzer Amulet with the Watchman (NCT03399851).

Randomized Controlled Trials

PRAGUE-17 Trial

As described above, the PRAGUE-17 RCT found use of LAAC (Watchman device or the Amplatzer Amulet) noninferior to direct oral anticoagulants for the primary composite endpoint in high-risk patients with AF.[27] The primary endpoint was a composite of ischemic or hemorrhagic stroke or TIA, systemic embolism, clinically significant bleeding, cardiovascular death, or significant peri-procedural or device-related complications Although 61.3% of patient received an Amplatzer Amulet device, subgroup analyses by device type were not presented

which limits interpretation. One device-related death occurred with the Amulet device due to a pericardial effusion approximately 6 weeks after the procedure.

Observational Studies

Landmesser et al (2017) presented periprocedural (within 7 days of procedure) and early clinical outcomes (1 to 3 months postprocedure) from a multicenter registry of 1088 patients receiving the Amplatzer Amulet between June 2015 and September 2016.[64] Technical success was defined as implantation of the device in the correct position, which was reported for 1078 (99%) of the patients. A composite of ischemic stroke, systemic embolism, and cardiovascular death occurred in 7 (0.6%) patients during the periprocedural period and in 15 (1.4%) patients between 7 days postprocedure and 3 months follow up.

Landmesser et al (2018) and Hildick-Smith et al (2020) provided updated analyses on 950 patients and 864 patients from the registry series described above who had 1-year and 2-year follow-up data.[65,66] Oral anticoagulants were used by 6% of the patients at 3, 6, and 12 months postprocedure and 6.6% of patients at 2 years. At year 1, there were 29 ischemic strokes (27 patients), 9 patients experiencing a TIA, and no systemic embolisms reported. At year 2, there were 42 ischemic strokes (39 patients), 20 TIA events (16 patients; 9 events over the first year and 11 over the second year) and no systemic embolisms reported. The annualized bleeding rate was 10.1% per year in year 1 (103 events per 1016 patient-years) and 4.0% per year in year 2 (37 events per 917 patient-years). The proportion of patients experiencing a major bleeding event was 8.0% over the first year (87 of 1088 patients) and 3.2% over the second year (31 of 958 patients). The DRT rate was 1.6% at 2 years, with 19 events in 17 patients. There were 91 and 70 deaths reported in the first and second years, respectively, with 55 deaths considered cardiovascular-related, 71 non-cardiovascular-related, and 35 with unknown causes.

Nielsen-Kudsk et al (2021) compared patients from the Amulet Observational Registry described above (n=1088) with a successful LAAC (n=1078) compared with a control cohort of patients with AF treated with direct oral anticoagulants (n=1184).[67] The direct oral anticoagulant cohort consisted of patients selected by propensity score matching based on CHA_2DS_2-VASc and HAS-BLED covariates among patients from Danish registries. The primary outcome was a composite of ischemic stroke, major bleeding, or all-cause mortality at 2 years. At baseline, the CHA_2DS_2-VASc scores were 4.2 and 4.3 and the HAS-BLED scores were 3.3 and 3.4 in the LAAC and direct oral anticoagulant groups, respectively. At 2 years follow-up, 58% of patients had discontinued the direct oral anticoagulant. The primary outcome of ischemic stroke, major bleeding, and mortality was lower with LAAC (256 events; 14.5 event rate per 100 patient-years) compared with the direct oral anticoagulant group (461 events; 25.7 event rate per 100 patient-years) (HR, 0.57; 95% CI, 0.49 to 0.67). Ischemic stroke was not significantly different between groups (HR, 1.11; 95% CI, 0.71 to 1.75). Major bleeding (HR, 0.62; 95% CI, 0.49 to 0.79), all-cause mortality (HR, 0.53; 95% CI, 0.43 to 0.64), and cardiovascular mortality (HR, 0.51; 95% CI, 0.37 to 0.70) were reduced with LAAC compared to direct oral anticoagulants.

Nonrandomized Comparative Studies

Gloekler et al (2015) reviewed records from 2 university hospitals' occlusion registries and conducted a retrospective analysis comparing the last 50 consecutive patients receiving the cardiac plug with the first 50 consecutive patients receiving the Amulet.[63] Follow-up

examinations were performed between 4 to 6 months post-procedure. No significant differences between the 2 devices were detected in mortality, neurologic events, late pericardial effusions, major bleeding, device leaks, or device thrombi. Interpretation of these results is limited by the small sample size and short follow-up period.

Al-Kassou et al (2017) presented periprocedural and 2 to 3 month followup data for patients undergoing LAA occlusion with the Amplatzer cardiac plug and the Amplatzer Amulet.[68] Periprocedural data was available for 99 patients receiving the cardiac plug and for 97 patients receiving the Amulet. Use of the Amulet was associated with significantly lower fluoroscopy time, lower radiation dose, and reduced amount of contrast dye. Occurrence of adverse events during the perioprocedural period were comparable. Transesophageal echocardiographic followup data at 2 to 3 months was available for 81 patients receiving the cardiac plug and for 82 patients receiving the Amulet. None of the patients experienced DRT during this followup. Minor leaks were detected in 12 (15%) patients receiving the cardiac plug and in 4 (5%) patients receiving the Amulet (p=0.03).

Section Summary: Amplatzer Cardiac Plug Device and Amplatzer Amulet
One RCT has evaluated use of LAAC with either the Amplatzer Amulet or Watchman device; however, subgroup analyses were not performed, limiting study interpretation. There are no RCTs of the Amplatzer device alone for LAAC. There are 2 nonrandomized studies comparing the first generation Amplatzer cardiac plug with the second generation Amplatzer Amulet, 1 of which reported procedural advantages of the Amulet over the cardiac plug. Both nonrandomized comparator studies reported no difference in clinical outcomes at first follow-up, 2 to 6 months. The remaining evidence consists of observational studies. One cohort study based on registry data found that the Amulet device reduced the composite of ischemic stroke, major bleeding, and all-cause mortality compared to direct oral anticoagulants. The non-randomized comparator studies and the observational studies are insufficient to draw conclusions about treatment efficacy. There is an ongoing trial comparing the Amplatzer Amulet with the Watchman (NCT03399851).

SUMMARY OF EVIDENCE
For individuals who have AF who are at increased risk for embolic stroke who receive the Watchman percutaneous LAAC device, the evidence includes 2 RCTs and meta-analyses of these trials. Relevant outcomes are overall survival, morbid events, and treatment-related morbidity. The most relevant evidence comes from 2 industry-sponsored RCTs that compared the Watchman device with anticoagulation alone. One trial reported noninferiority on a composite outcome of stroke, cardiovascular/unexplained death, or systemic embolism after 2 years of follow-up, with continued benefits with the Watchman device after 4 years of follow-up. The second trial did not demonstrate noninferiority for the same composite outcome, but did demonstrate noninferiority of the Watchman device to warfarin for late ischemic stroke and systemic embolization. Patient-level meta-analyses at 5-year follow-up for the 2 trials reported that the Watchman device is noninferior to warfarin on the composite outcome of stroke, systemic embolism, and cardiovascular death. Also, the Watchman was associated lower rates in major bleeding, particularly hemorrhagic stroke, and mortality over the long term. The evidence also indicates that the Watchman device is efficacious in preventing stroke in the subset of patients with AF who are at increased risk for embolic stroke. Among patients in whom the long-term risk of systemic anticoagulation exceeds the procedural risk of device

implantation, the net health outcome will be improved. The evidence is sufficient to determine that the technology results in an improvement in the net health outcome.

For individuals who have AF who are at increased risk for embolic stroke who receive a percutaneous LAAC device other than the Watchman device (eg, Lariat or Amplatzer), the evidence includes several nonrandomized comparator studies and uncontrolled observational studies. Relevant outcomes are overall survival, morbid events, and treatment-related morbidity. One nonrandomized study which compared outcomes among patients undergoing LAAC with the Lariat device with patients receiving anticoagulant or antiplatelet therapy, reported fewer thromboembolic events in the group receiving the Lariat device. Although a RCT evaluated use of LAAC with either the Amplatzer Amulet or Watchman device, subgroup analyses were not performed, limiting study interpretation. One cohort study based on registry data found that the Amulet device reduced the composite of ischemic stroke, major bleeding, and all-cause mortality compared to direct oral anticoagulants. Two nonrandomized studies compared the Amplatzer cardiac plug with the Amplatzer Amulet. While the Amulet may be technically easier to implant, clinical outcomes were similar between the 2 groups. The remaining evidence consists of observational studies of these devices have reported high procedural success, but also numerous complications. In addition, these devices do not have U.S. Food and Drug Administration approval for LAAC. The evidence is insufficient to determine that the technology results in an improvement in the net health outcome.

SUPPLEMENTAL INFORMATION

The purpose of the following information is to provide reference material. Inclusion does not imply endorsement or alignment with the evidence review conclusions.

Clinical Input Received From Physician Specialty Societies and Academic Medical Centers

In response to requests, Blue Cross Blue Shield Association received input from 1 physician specialty society (2 responses) and 4 academic medical centers, one of which provided 4 responses, for a total of 8 responses, while this policy was under their review in 2015. Input generally supported the use of a left atrial appendage closure device approved by the Food and Drug Administration for patients with an increased risk of stroke and systemic embolism, based on $CHADS_2$ or CHA_2DS_2-VASc score. Systemic anticoagulation therapy was recommended, but the long-term risks of systemic anticoagulation outweigh the risks of the device implantation.

Practice Guidelines and Position Statements

Guidelines or position statements will be considered for inclusion in ‘Supplemental Information if they were issued by, or jointly by, a US professional society, an international society with US representation, or National Institute for Health and Care Excellence (NICE). Priority will be given to guidelines that are informed by a systematic review, include strength of evidence ratings, and include a description of management of conflict of interest.

American Heart Association

In 2019, the American Heart Association, in collaboration with the American College of Cardiology and the Hearth Rhythm Society published an update of their guideline for the management of patients with atrial fibrillation (AF).[69] A new recommendation in the guideline

states: "Percutaneous LAA [left atrial appendage] occlusion may be considered in patients with AF at increased risk of stroke who have contraindications to long-term anticoagulation." The class of recommendation is IIb and the level of evidence is B_NR (moderate quality of evidence, non-randomized). No other LAA closure devices are mentioned in the guideline.

American College of Chest Physicians
In 2018, the American College of Chest Physicians (CHEST) guideline made the following recommendation regarding LAA occlusion and oral anticoagulation: "In patients with AF at high risk of ischemic stroke who have absolute contraindications for OAC [oral anticoagulation], we suggest using LAA occlusion (Weak recommendation, low quality evidence)."[3]

Guideline Comparison
In 2017, Andrade et al provided the following summary (Table 3) comparing guidelines by American, Canadian, and European societies on left atrial appendage exclusion and closure for the management of atrial fibrillation.[70]

Table 3. Comparison of American, Canadian, and European Guidelines on LAA Exclusion/Closure

Procedure	AHA/ACC/HRS	CCS	ESC
Surgical LAA closure (excision or obliteration of LAA)	May be considered in patients undergoing cardiac surgery (IIb)	Should be considered as part of surgical ablation of AF associated with mitral, aortic valve, or coronary artery bypass surgery	May be considered in patients undergoing cardiac surgery (IIb)More data needed to confirm safety and efficacy of thoracoscopic exclusion
Percutaneous LAA exclusion	No recommendation	Not be used, except in research or in systematically documented use protocols in patients at high risk of stroke (CHADS2 ≥2) and antithrombotic therapy precluded	May be considered in patients with contraindications for long term anticoagulant treatment (IIb)

Adapted from Andrade et al (2017).70,
ACC: American College of Cardiology; AF: atrial fibrillation; AHA: American Heart Association; CCS: Canadian Cardiovascular Society; CHADS2: Congestive
Heart Failure, Hypertension, Age, Diabetes, Stroke/Transient Ischemic Attack; ESC: European Society of Cardiology; HRS: Heart Rhythm Society; LAA: left atrial
appendage.

U.S. PREVENTIVE SERVICES TASK FORCE RECOMMENDATIONS
Not applicable.

ONGOING AND UNPUBLISHED CLINICAL TRIALS
Some currently ongoing and unpublished trials that might influence this policy are listed in Table 4.

Table 4: Summary of Key Trials

NCT No.	Trial Name	Planned Enrollment	Completion Date
Ongoing			

NCT03276169	Left Atrial Function Changes after Left Atrial Appendage Closure in Patients with Persistent Atrial Fibrillation	105	Nov 2020
NCT02513797[a]	aMAZE Study: LAA Ligation with the LARIAT Suture Delivery System as Adjunctive to Pulmonary Vein Isolation for Persistent Atrial Fibrillation (aMAZE)	600	Dec 2021
NCT03204695[a]	A Prospective, Multicenter, Non-Randomized, Post-market Clinical Follow-up Study to Confirm Safety and Performance of the Coherex WaveCrest Left Atrial Appendage Occlusion System in Patients with Non-valvular Atrial Fibrillation	65	Mar 2022
NCT03463317	Left Atrial Appendage CLOSURE in Patients With Atrial Fibrillation at High Risk of Stroke and Bleeding Compared to Medical Therapy: a Prospective Randomized Clinical Trial	1512	Feb 2023
NCT02964208[a]	AMPLATZER LAA Occluder Post Approval Study (PAS)	1000	Oct 2023
NCT02879448	AMPLATZER™ Amulet™ Left Atrial Appendage Occluder Randomized Controlled Trial	1878	Aug 2024
NCT03399851	Comparison of Amplatzer Amulet vs. Watchman Device in Patients Undergoing Left Atrial Appendage Closure: the SWISS-APERO Randomized Clinical Trial	2000	Dec 2025
NCT03302494[a]	WAveCrest Vs. Watchman TranssEptal LAA Closure to REduce AF-Mediated STroke 2 (WAVECREST2)	1250	Dec 2028
NCT03309332[a]	OSB Lead-AMPLATZER PFO Occluder New Enrollment PAS	1214	Dec 2027
NCT03795298	Comparison of Anticoagulation with Left Atrial Appendage Closure After AF Ablation (OPTION)	1600	Nov 2024
NCT04394546	WATCHMAN FLX Versus NOAC for Embolic ProtectION in in the Management of Patients With Non-Valvular Atrial Fibrillation	3000	Dec 2027
NCT04226547	Clinical Trial of Atrial Fibrillation Patients Comparing Left Atrial Appendage Occlusion Therapy to Non-vitamin K Antagonist Oral Anticoagulants	2650	April 2029
Unpublished			
NCT01118299	AMPLATZER Cardiac Plug Clinical Trial	3000	Dec 2018 (updated 02/01/19)
NCT02681042	Left Atrial Appendage Closure with SentreHeart Lariat Device	9	May 2018 (updated 02/21/21)

NCT: national clinical trial.
[a] indicates industry-sponsored study.

Government Regulations
National:

National Coverage Determination (NCD) for Percutaneous Left Atrial Appendage Closure (LAAC) (20.34)
Effective Date of the Version: 2/8/2016
Implementation Date: 10/3/2016

Indications and Limitations of Coverage

B. Nationally Covered Indications

The Centers for Medicare & Medicaid Services (CMS) covers percutaneous LAAC for non-valvular atrial fibrillation (NVAF) through Coverage with Evidence Development (CED) with the following conditions:

a. LAAC devices are covered when the device has received Food and Drug Administration (FDA) Premarket Approval (PMA) for that device's FDA-approved indication and meet all of the conditions specified below:

The patient must have:

- A CHADS2 score ≥2 (Congestive heart failure, Hypertension, Age > 75, Diabetes, Stroke/transient ischemia attack/thromboembolism) or CHA2DS2-VASc score ≥ 3 (Congestive heart failure, Hypertension, Age ≥ 65, Diabetes, Stroke/transient ischemia attack/thromboembolism, Vascular disease, Sex category)
- A formal shared decision making interaction with an independent non-interventional physician using an evidence-based decision tool on oral anticoagulation in patients with NVAF prior to LAAC. Additionally, the shared decision making interaction must be documented in the medical record.
- A suitability for short-term warfarin but deemed unable to take long-term oral anticoagulation following the conclusion of shared decision making, as LAAC is only covered as a second line therapy to oral anticoagulants. The patient (preoperatively and postoperatively) is under the care of a cohesive, multidisciplinary team (MDT) of medical professionals. The procedure must be furnished in a hospital with an established structural heart disease (SHD) and/or electrophysiology (EP) program.

The procedure must be performed by an interventional cardiologist(s), electrophysiologist(s), or cardiovascular surgeon (s) that
meet the following criteria:<.p>

- Has received training prescribed by the manufacturer on the safe and effective use of the device prior to performing LAAC; and,
- Has performed ≥ 25 interventional cardiac procedures that involve transeptal puncture through an intact septum; and,
- Continues to perform ≥ 25 interventional cardiac procedures that involve transeptal puncture through an intact septum, of which at least 12 are LAAC, over a 2-year period.

The patient is enrolled in, and the MDT and hospital must participate in, a prospective, national, audited registry that: 1) consecutively enrolls LAAC patients, and, 2) tracks the following annual outcomes for each patient for a period of at least 4 years from the time of the LAAC:

- Operator-specific complications
- Device-specific complications including device thrombosis
- Stroke, adjudicated, by type
- Transient Ischemic Attack (TIA)
- Systemic embolism
- Death
- Major bleeding, by site and severity

[See the NCD for specific information related to registry criteria.]

C. Nationally Non-Covered Indications

LAAC is non-covered for the treatment of NVAF when not furnished under CED according to the above-noted criteria.

[This NCD was last reviewed February 2016.]

Local:

There is no local coverage determination. Refer to the NCD.

(The above Medicare information is current as of the review date for this policy. However, the coverage issues and policies maintained by the Centers for Medicare & Medicare Services [CMS, formerly HCFA] are updated and/or revised periodically. Therefore, the most current CMS information may not be contained in this document. For the most current information, the reader should contact an official Medicare source.)

Pre-Consolidation Medical Policy History

Original Policy Date	Comments
BCN: N/A	Revised: N/A
BCBSM: 2/16/01	Revised: N/A

BLUE CARE NETWORK BENEFIT COVERAGE
POLICY: PERCUTANEOUS LEFT ATRIAL APPENDAGE CLOSURE DEVICES FOR STROKE PREVENTION IN ATRIAL FIBRILLATION

1. Coverage Determination:

Commercial HMO (includes Self-Funded groups unless otherwise specified)	Covered; criteria apply
BCNA (Medicare Advantage)	See Government Regulations section.
BCN65 (Medicare Complementary)	Coinsurance covered if primary Medicare covers the service.

2. Administrative Guidelines:

- The member's contract must be active at the time the service is rendered.
- The service must be authorized by the member's PCP except for Self-Referral Option (SRO) members seeking Tier 2 coverage.
- Services must be performed by a BCN-contracted provider, if available, except for Self-Referral Option (SRO) members seeking Tier 2 coverage.
- Payment is based on BCN payment rules, individual certificate and certificate riders.
- Appropriate copayments will apply. Refer to certificate and applicable riders for detailed information.
- CPT - HCPCS codes are used for descriptive purposes only and are not a guarantee of coverage.
